Notes:

1. L = V_{IL}, H = V_{IH}, X = H or L, High-Z = High impedance. Refer to the DC Characteristics.
2. Command writes involving block erase, full chip erase, (page buffer) program or OTP program are reliably executed when F-V_{PP} = V_{PPH1/2} and F-V_{CC} = 2.7V to 3.3V.
Block erase, full chip erase, (page buffer) program or OTP program with F-V_{PP} < V_{PPH1/2} (Min.) produce spurious results and should not be attempted.
3. Never hold F- \overline{OE} low and F- \overline{WE} low at the same timing.
4. Refer to Section 5. Command Definitions for Flash Memory valid D_{IN} during a write operation.
5. F- \overline{WP} set to V_{IL} or V_{IH}.
6. Electricity consumption of Flash Memory is lowest when F- \overline{RST} = GND ±0.2V.

Notes:

1. "X" denotes the operation available.
2. Configurative Partition Dual Work Restrictions:
 Status register reflects partition state, not WSM (Write State Machine) state - this allows a status register for each partition.
 Only one partition can be erased or programmed at a time - no command queuing.
 Commands must be written to an address within the block targeted by that command.

X=Any valid address within the device.
PA=Address within the selected partition.
IA=Identifier codes address (See 5.2 Identifier Codes and OTP Address for Read Operation).
QA=Query codes address. Refer to the LH28F320BF, LH28F640BF, LH28F128BF series Appendix for details.
BA=Address within the block being erased, set/cleared block lock bit or set block lock-down bit.
WA=Address of memory location for the Program command or the first address for the Page Buffer Program command.
OA=Address of OTP block to be read or programmed (See 5.3 OTP Block Address Map).
PCRC=Partition configuration register code presented on the address A₀-A₁₅.
- ID=Data read from identifier codes (See 5.2 Identifier Codes and OTP Address for Read Operation).
QD=Data read from query database. Refer to the LH28F320BF, LH28F640BF, LH28F128BF series Appendix for details.
SRD=Data read from status register. (See 6. Status Register Definition for a description of the status register bits.)
WD=Data to be programmed at location WA. Data is latched on the rising edge of F- \overline{WE} or F- \overline{CE} (whichever goes high first) during command write cycles.
OD=Data within OTP block. Data is latched on the rising edge of F- \overline{WE} or F- \overline{CE} (whichever goes high first) during command write cycles.
N-1=N is the number of the words to be loaded into a page buffer.
- Following the Read Identifier Codes/OTP command, read operations access manufacturer code, device code, block lock configuration code, partition configuration register code and the data within OTP block (See 5.2 Identifier Codes and OTP Address for Read Operation).
The Read Query command is available for reading CFI (Common Flash Interface) information.
- Block erase, full chip erase or (page buffer) program cannot be executed when the selected block is locked. Unlocked block can be erased or programmed when F-RST is V_{IH}.

6. Either 40H or 10H are recognized by the CUI (Command User Interface) as the program setup.
7. Following the third bus cycle, input the program sequential address and write data of “N” times. Finally, input the any valid address within the target block to be programmed and the confirm command (D0H). Refer to the LH28F320BF, LH28F640BF, LH28F128BF series Appendix for details.
8. If the program operation in one partition is suspended and the erase operation in other partition is also suspended, the suspended program operation should be resumed first, and then the suspended erase operation should be resumed next.
9. Full chip erase and OTP program operations can not be suspended. The OTP Program command can not be accepted while the block erase operation is being suspended.
10. Following the Clear Block Lock Bit command, block which is not locked-down is unlocked when $F\text{-}\overline{WP}$ is V_{IL} .
When $F\text{-}\overline{WP}$ is V_{IH} , lock-down bit is disabled and the selected block is unlocked regardless of lock-down configuration.
11. Commands other than those shown above are reserved by SHARP for future device implementations and should not be used.

5.4 Functions of Block Lock⁽¹⁾ and Block Lock-Down

Current State					Erase/Program Allowed ⁽³⁾
State	F- \overline{WP}	DQ ₁ ⁽²⁾	DQ ₀ ⁽²⁾	State Name	
[000]	0	0	0	Unlocked	Yes
[001] ⁽⁴⁾	0	0	1	Locked	No
[011]	0	1	1	Locked-down	No
[100]	1	0	0	Unlocked	Yes
[101] ⁽⁴⁾	1	0	1	Locked	No
[110] ⁽⁵⁾	1	1	0	Lock-down Disable	Yes
[111]	1	1	1	Lock-down Disable	No

Notes:

1. OTP (One Time Program) block has the lock function which is different from those described above.
2. DQ₀ = 1: a block is locked; DQ₀ = 0: a block is unlocked.
DQ₁ = 1: a block is locked-down; DQ₁ = 0: a block is not locked-down.
3. Erase and program are general terms, respectively, to express: block erase, full chip erase and (page buffer) program operations.
4. At power-up or device reset, all blocks default to locked state and are not locked-down, that is, [001] (F- \overline{WP} = 0) or [101] (F- \overline{WP} = 1), regardless of the states before power-off or reset operation.
5. When F- \overline{WP} is driven to V_{IL} in [110] state, the state changes to [011] and the blocks are automatically locked.

5.5 Block Locking State Transitions upon Command Write⁽⁴⁾

Current State				Result after Lock Command Written (Next State)		
State	F- \overline{WP}	DQ ₁	DQ ₀	Set Lock ⁽¹⁾	Clear Lock ⁽¹⁾	Set Lock-down ⁽¹⁾
[000]	0	0	0	[001]	No Change	[011] ⁽²⁾
[001]	0	0	1	No Change ⁽³⁾	[000]	[011]
[011]	0	1	1	No Change	No Change	No Change
[100]	1	0	0	[101]	No Change	[111] ⁽²⁾
[101]	1	0	1	No Change	[100]	[111]
[110]	1	1	0	[111]	No Change	[111] ⁽²⁾
[111]	1	1	1	No Change	[110]	No Change

Notes:

1. “Set Lock” means Set Block Lock Bit command, “Clear Lock” means Clear Block Lock Bit command and “Set Lock-down” means Set Block Lock-Down Bit command.
2. When the Set Block Lock-Down Bit command is written to the unlocked block (DQ₀ = 0), the corresponding block is locked-down and automatically locked at the same time.
3. “No Change” means that the state remains unchanged after the command written.
4. In this state transitions table, assumes that F- \overline{WP} is not changed and fixed V_{IL} or V_{IH}.

5.6 Block Locking State Transitions upon F- \overline{WP} Transition⁽⁴⁾

Previous State	Current State				Result after F- \overline{WP} Transition (Next State)	
	State	F- \overline{WP}	DQ ₁	DQ ₀	F- \overline{WP} = 0→1 ⁽¹⁾	F- \overline{WP} = 1→0 ⁽¹⁾
-	[000]	0	0	0	[100]	-
-	[001]	0	0	1	[101]	-
[110] ⁽²⁾	[011]	0	1	1	[110]	-
Other than [110] ⁽²⁾					[111]	-
-	[100]	1	0	0	-	[000]
-	[101]	1	0	1	-	[001]
-	[110]	1	1	0	-	[011] ⁽³⁾
-	[111]	1	1	1	-	[011]

Notes:

1. “F- \overline{WP} = 0→1” means that F- \overline{WP} is driven to V_{IH} and “F- \overline{WP} = 1→0” means that F- \overline{WP} is driven to V_{IL}.
2. State transition from the current state [011] to the next state depends on the previous state.
3. When F- \overline{WP} is driven to V_{IL} in [110] state, the state changes to [011] and the blocks are automatically locked.
4. In this state transitions table, assumes that lock configuration commands are not written in previous, current and next state.

V _{LKO}	F-V _{CC} Lockout Voltage		1.5			V	

Notes:

- V_{CC} includes both F-V_{CC} and S-V_{CC}.
- All currents are in RMS unless otherwise noted. Typical values are the reference values at V_{CC} = 3.0V and T_A = +25°C unless V_{CC} is specified.
- I_{CCWS} and I_{CCES} are specified with the device de-selected. If read or (page buffer) program is executed while in block erase suspend mode, the device's current draw is the sum of I_{CCES} and I_{CCR} or I_{CCW}. If read is executed while in (page buffer) program suspend mode, the device's current draw is the sum of I_{CCWS} and I_{CCR}.
- Block erase, full chip erase, (page buffer) program and OTP program are inhibited when F-V_{PP} ≤ V_{PPLK}, and not guaranteed in the range between V_{PPLK} (max.) and V_{PPH1} (min.), between V_{PPH1} (max.) and V_{PPH2} (min.) and above V_{PPH2} (max.).
- The Automatic Power Savings (APS) feature automatically places the device in power save mode after read cycle completion. Standard address access timings (t_{AVQV}) provide new data when addresses are changed.
- Sampled, not 100% tested.
- F-V_{PP} is not used for power supply pin. With F-V_{PP} ≤ V_{PPLK}, block erase, full chip erase, (page buffer) program and OTP program cannot be executed and should not be attempted.
Applying 12V ±0.3V to F-V_{PP} provides fast erasing or fast programming mode. In this mode, F-V_{PP} is power supply pin and supplies the memory cell current for block erasing and (page buffer) programming. Use similar power supply trace widths and layout considerations given to the V_{CC} power bus.
Applying 12V ±0.3V to F-V_{PP} during erase/program can only be done for a maximum of 1000 cycles on each block. F-V_{PP} may be connected to 12V ±0.3V for a total of 80 hours maximum.
- The operating current in dual work is the sum of the operating current (read, erase, program) in each plane.
- Includes F-RY/ \overline{BY} .

Notes:

1. The timing characteristics for reading the status register during block erase, full chip erase, (page buffer) program and OTP program operations are the same as during read-only operations. See the AC Characteristics for read cycle.
2. A write operation can be initiated and terminated with either F- \overline{CE} or F- \overline{WE} .

4. Write pulse width (t_{WP}) is defined from the falling edge of F- \overline{CE} or F- \overline{WE} (whichever goes low last) to the rising edge of F- \overline{CE} or F- \overline{WE} (whichever goes high first). Hence, t_{WP}=t_{WLWH}=t_{ELEH}=t_{WLEH}=t_{ELWH}.
5. Write pulse width high (t_{WPH}) is defined from the rising edge of F- \overline{CE} or F- \overline{WE} (whichever goes high first) to the falling edge of F- \overline{CE} or F- \overline{WE} (whichever goes low last). Hence, t_{WPH}=t_{WHWL}=t_{EHEL}=t_{WHEL}=t_{EHWL}.
6. F-V_{PP} should be held at F-V_{PP}=V_{PPH1/2} until determination of block erase, full chip erase, (page buffer) program or OTP program success (SR.1/3/4/5=0).

4. A latency time is required from writing suspend command (F- \overline{WE} or F- \overline{CE} going high) until SR.7 going "1" or F-RY/ \overline{BY} going High-Z.
5. If the interval time from a Block Erase Resume command to a subsequent Block Erase Suspend command is shorter than t_{ERES} and its sequence is repeated, the block erase operation may not be finished.

Notes:

- A write occurs during the overlap of a low S- $\overline{\text{CE}}_1$, a high S-CE₂ and a low S- $\overline{\text{WE}}$.
A write begins at the latest transition among S- $\overline{\text{CE}}_1$ going low, S-CE₂ going high and S- $\overline{\text{WE}}$ going low.
A write ends at the earliest transition among S- $\overline{\text{CE}}_1$ going high, S-CE₂ going low and S- $\overline{\text{WE}}$ going high.
 t_{wp} is measured from the beginning of write to the end of write.
- t_{cw} is measured from the later of S- $\overline{\text{CE}}_1$ going low or S-CE₂ going high to the end of write.

- During this period DQ pins are in the output state, therefore the input signals of opposite phase to the outputs must not be applied.
- If S- $\overline{\text{CE}}_1$ goes low or S-CE₂ goes high simultaneously with S- $\overline{\text{WE}}$ going low or after S- $\overline{\text{WE}}$ going low, the outputs remain in high impedance state.
- If S- $\overline{\text{CE}}_1$ goes high or S-CE₂ goes low simultaneously with S- $\overline{\text{WE}}$ going high or before S- $\overline{\text{WE}}$ going high, the outputs remain in high impedance state.

Data Retention timing chart ($S\text{-CE}_2$ Controlled)

15. Notes

This product is a stacked CSP package that a 32M (x16) bit Flash Memory and a 8M (x16) bit SRAM are assembled into.

- Supply Power

Maximum difference (between F- V_{CC} and S- V_{CC}) of the voltage is less than 0.3V.

- Power Supply and Chip Enable of Flash Memory and SRAM (F- \overline{CE} , S- \overline{CE}_1 , S- CE_2)

S- \overline{CE}_1 should not be “low” and S- CE_2 should not be “high” when F- \overline{CE} is “low” simultaneously.

If the two memories are active together, possibly they may not operate normally by interference noises or data collision on DQ bus.

Both F- V_{CC} and S- V_{CC} are needed to be applied by the recommended supply voltage at the same time except SRAM data retention mode.

- Power Up Sequence

When turning on Flash memory power supply, keep F- \overline{RST} “low”. After F- V_{CC} reaches over 2.7V, keep F- \overline{RST} “low” for more than 100 nsec.

- Device Decoupling

The power supply is needed to be designed carefully because one of the SRAM and the Flash Memory is in standby mode when the other is active. A careful decoupling of power supplies is necessary between SRAM and Flash Memory. Note peak current caused by transition of control signals (F- \overline{CE} , S- \overline{CE}_1 , S- CE_2).

16. Flash Memory Data Protection

Noises having a level exceeding the limit specified in the specification may be generated under specific operating conditions on some systems. Such noises, when induced onto $F\text{-}\overline{WE}$ signal or power supply, may be interpreted as false commands and causes undesired memory updating. To protect the data stored in the flash memory against unwanted writing, systems operating with the flash memory should have the following write protect designs, as appropriate:

■ The below describes data protection method.

1. Protection of data in each block

- Any locked block by setting its block lock bit is protected against the data alternation. When $F\text{-}\overline{WP}$ is low, any locked-down block by setting its block lock-down bit is protected from lock status changes.
By using this function, areas can be defined, for example, program area (locked blocks), and data area (unlocked blocks).
- For detailed block locking scheme, see Chapter 5. Command Definitions for Flash Memory.

2. Protection of data with $F\text{-}V_{PP}$ control

- When the level of $F\text{-}V_{PP}$ is lower than V_{PPLK} ($F\text{-}V_{PP}$ lockout voltage), write functions to all blocks including OTP block are disabled. All blocks are locked and the data in the blocks are completely protected.

3. Protection of data with $F\text{-}\overline{RST}$

- Especially during power transitions such as power-up and power-down, the flash memory enters reset mode by bringing $F\text{-}\overline{RST}$ to low, which inhibits write operation to all blocks including OTP block.
- For detailed description on $F\text{-}\overline{RST}$ control, see Chapter 12.6 AC Electrical Characteristics for Flash Memory, Reset Operations.

■ Protection against noises on $F\text{-}\overline{WE}$ signal

To prevent the recognition of false commands as write commands, system designer should consider the method for reducing noises on $F\text{-}\overline{WE}$ signal.

17. Design Considerations

1. Power Supply Decoupling

To avoid a bad effect to the system by flash memory power switching characteristics, each device should have a 0.1 μ F ceramic capacitor connected between its F-V_{CC} and GND and between its F-V_{PP} and GND.

Low inductance capacitors should be placed as close as possible to package leads.

2. F-V_{PP} Trace on Printed Circuit Boards

Updating the memory contents of flash memories that reside in the target system requires that the printed circuit board designer pay attention to the F-V_{PP} Power Supply trace. Use similar trace widths and layout considerations given to the F-V_{CC} power bus.

3. The Inhibition of Overwrite Operation

Please do not execute reprogramming "0" for the bit which has already been programmed "0". Overwrite operation may generate unerasable bit.

In case of reprogramming "0" to the data which has been programmed "1".

- Program "0" for the bit in which you want to change data from "1" to "0".
- Program "1" for the bit which has already been programmed "0".

For example, changing data from "1011110110111101" to "1010110110111100" requires "111011111111110" programming.

4. Power Supply

Block erase, full chip erase, (page buffer) program and OTP program with an invalid F-V_{PP} (See Chapter 11. DC Electrical Characteristics) produce spurious results and should not be attempted.

Device operations at invalid F-V_{CC} voltage (See Chapter 11. DC Electrical Characteristics) produce spurious results and should not be attempted.

A-3 STATUS REGISTER READ OPERATIONS

If AC timing for reading the status register described in specifications is not satisfied, a system processor can check the status register bit SR.15 instead of SR.7 to determine when the erase or program operation has been completed.

Table A-3-1. Status Register Definition (SR.15 and SR.7)

<p>SR.15 = WRITE STATE MACHINE STATUS: (DQ₁₅) 1 = Ready in All Partitions 0 = Busy in Any Partition</p> <p>SR.7 = WRITE STATE MACHINE STATUS FOR EACH PARTITION: (DQ₇) 1 = Ready in the Addressed Partition 0 = Busy in the Addressed Partition</p>	<p>NOTES:</p> <p>SR.15 indicates the status of WSM (Write State Machine). If SR.15="0", erase or program operation is in progress in any partition.</p> <p>SR.7 indicates the status of the partition. If SR.7="0", erase or program operation is in progress in the addressed partition. Even if the SR.7 is "1", the WSM may be occupied by the other partition.</p>
